1. Data Description Overview

1.1 Dataset Citation & Source

Source: [UCI Machine Learning Repository — EEG Eye State](#)

All data is from one continuous EEG measurement with the Emotiv EEG Neuroheadset. The duration of the measurement was 117 seconds. The eye state was detected via a camera during the EEG measurement and added later manually to the file after analysing the video frames. '1' indicates the eye-closed and '0' the eye-open state. All values are in chronological order with the first measured value at the top of the data.

1.2 Dataset Loading

The dataset is loaded from `dataset/eeg_data_og.csv` .

Property	Value
Samples	14980
Features	14
Target Column	eyeDetection
Sampling Rate	128 Hz
Recording Duration	117.0 seconds

1.3 Variable Classification & Electrode Positions

Numerical Variables (Continuous): 14 EEG electrode channels recording voltage in micro-volts (μV). The Emotiv EPOC headset uses a modified 10-20 international system for electrode placement. Each electrode captures electrical activity from a specific cortical region.

Electrode	Type	10-20 Position	Brain Region	Functional Significance
AF3	Continuous (float64)	Anterior Frontal Left	Prefrontal Cortex	Executive function, attention
F7	Continuous (float64)	Frontal Left Lateral	Left Temporal-Frontal	Language processing
F3	Continuous (float64)	Frontal Left	Left Frontal Lobe	Motor planning, positive affect
FC5	Continuous (float64)	Fronto-Central Left	Left Motor-Frontal	Motor preparation
T7	Continuous (float64)	Temporal Left	Left Temporal Lobe	Auditory processing, memory
P7	Continuous (float64)	Parietal Left	Left Parietal-Temporal	Visual-spatial processing
O1	Continuous (float64)	Occipital Left	Left Visual Cortex	Visual processing
O2	Continuous (float64)	Occipital Right	Right Visual Cortex	Visual processing
P8	Continuous (float64)	Parietal Right	Right Parietal-Temporal	Spatial attention
T8	Continuous (float64)	Temporal Right	Right Temporal Lobe	Face / emotion recognition

Electrode	Type	10-20 Position	Brain Region	Functional Significance
FC6	Continuous (float64)	Fronto-Central Right	Right Motor-Frontal	Motor preparation
F4	Continuous (float64)	Frontal Right	Right Frontal Lobe	Motor planning, negative affect
F8	Continuous (float64)	Frontal Right Lateral	Right Temporal-Frontal	Emotion, social cognition
AF4	Continuous (float64)	Anterior Frontal Right	Prefrontal Cortex	Executive function, attention

Categorical Variable (Target):

Variable	Type	Values	Description
eyeDetection	Binary (int)	0 = Open, 1 = Closed	Eye state detected via camera during recording

1.4 Basic Statistics

Descriptive statistics for all 14 EEG channels (µV).

Channel	Count	Mean	Std	Min	25%	50%	75%	Max	Mode
AF3	14980	4321.92	2492.07	1030.77	4280.51	4294.36	4311.79	309231.00	4291.79
F7	14980	4009.77	45.94	2830.77	3990.77	4005.64	4023.08	7804.62	4003.59
F3	14980	4264.02	44.43	1040.00	4250.26	4262.56	4270.77	6880.51	4263.59
FC5	14980	4164.95	5216.40	2453.33	4108.21	4120.51	4132.31	642564.00	4122.56
T7	14980	4341.74	34.74	2089.74	4331.79	4338.97	4347.18	6474.36	4332.31
P7	14980	4644.02	2924.79	2768.21	4611.79	4617.95	4626.67	362564.00	4616.41
O1	14980	4110.40	4600.93	2086.15	4057.95	4070.26	4083.59	567179.00	4072.31
O2	14980	4616.06	29.29	4567.18	4604.62	4613.33	4624.10	7264.10	4610.77
P8	14980	4218.83	2136.41	1357.95	4190.77	4199.49	4209.23	265641.00	4196.92
T8	14980	4231.32	38.05	1816.41	4220.51	4229.23	4239.49	6674.36	4224.62
FC6	14980	4202.46	37.79	3273.33	4190.26	4200.51	4211.28	6823.08	4195.38
F4	14980	4279.23	41.54	2257.95	4267.69	4276.92	4287.18	7002.56	4273.85
F8	14980	4615.21	1208.37	86.67	4590.77	4603.08	4617.44	152308.00	4603.08
AF4	14980	4416.44	5891.29	1366.15	4342.05	4354.87	4372.82	715897.00	4352.31

Note on Spike Artifacts: Some channels exhibit extremely large max values — orders of magnitude above the 75th percentile. These are likely **electrode spike artifacts** caused by momentary loss of contact, muscle movement, or impedance changes in the Emotiv headset. These extreme values will be addressed by the outlier removal step.

1.5 Class Distribution

Distribution of the target variable `eyeDetection` (per UCI: 0 = open, 1 = closed).

Eye State	Count	Percentage
Open (0)	8257	55.1%
Closed (1)	6723	44.9%

2. Data Imputation

Missing values are detected and filled using column-wise **median imputation** to preserve the statistical properties of each EEG channel.

Result: No missing values detected across any of the 14 EEG channels. The dataset is complete.

3. Data Visualization (Raw Data)

Visualizations of the raw EEG data before any preprocessing.

3.1 Class Balance

3.2 Correlation Heatmap

The correlation heatmap reveals linear relationships between EEG channels. Highly correlated channels may carry redundant information.

Note on spike artifacts: The raw dataset contains extreme hardware spike artifacts (e.g., AF3 max $\approx 309,231\ \mu\text{V}$, FC5 max $\approx 642,564\ \mu\text{V}$) with values **75–150 $\times$ the 99th percentile**. When multiple distant channels spike simultaneously (e.g., AF3 and P8 co-spike on ~ 82 samples), those extreme outliers dominate the Pearson calculation and produce **artificial $r \approx 1.00$** between electrodes that should be uncorrelated. The heatmap below is therefore computed on data **winsorized at the 1st–99th percentile** to expose the true inter-channel structure. The full preprocessing pipeline (IQR spike removal $\rightarrow$ bandpass filter) in Section 4 corrects this permanently.

3.3 Box Plots

Box plots highlight potential outliers beyond the 1.5x IQR whiskers.

The raw box plots are compressed by extreme spike artifacts. Below is a **zoomed view** clipped at the 1st–99th percentile range to reveal the actual distribution of most samples.

3.4 Histograms

Amplitude distributions per channel split by eye state.

3.5 Violin Plots

Violin plots combine box-plot summaries with kernel density estimates.

4. Signal Preprocessing

EEG signals contain artifacts from eye blinks, muscle movement, and electrode drift that must be removed before analysis. This section applies a two-stage cleaning pipeline in the **correct causal order**:

- 1. IQR spike removal first** — raw hardware spike artifacts (up to 715,897 μV) are removed *before* filtering. Applying `filtfilt` to spikes first smears them to neighbouring samples via the backward pass, inflating data loss from ~9% to ~19%.
- 2. Bandpass filter (0.5–45 Hz) second** — applied to the already spike-free signal so no artifact energy is convolved into the physiological EEG bands.

4.1 IQR Spike Removal (applied first, before filtering)

A **light IQR filter** (3.0x IQR, max 3 passes) removes hardware spike artifacts from the **raw** signal. Applying this step *before* filtering is critical: `filtfilt` convolves forward then backward, so a single spike at sample t would contaminate samples $t - N$ through $t + N$ after filtering. Removing spikes first keeps those neighbouring samples clean and reduces total data loss from ~19% to ~9%.

Threshold: $Q_3 + 3.0 \times IQR$ (wider than the traditional 1.5 $\times$ to preserve genuine EEG excursions while rejecting hardware glitches).

Channel	Lower Bound (μV)	Upper Bound (μV)
AF3	4186.67	4405.63
F7	3897.95	4113.34
F3	4193.35	4326.14
FC5	4047.69	4187.69

Channel	Lower Bound (µV)	Upper Bound (µV)
T7	4288.71	4389.23
P7	4570.24	4667.19
O1	3982.08	4157.92
O2	4549.24	4678.46
P8	4138.45	4260.53
T8	4164.62	4293.84
FC6	4127.70	4271.27
F4	4213.33	4338.98
F8	4517.41	4686.18
AF4	4260.00	4450.26

Metric	Value
Original samples	14980
After IQR removal	13606
Spike samples removed	1374
Removal %	9.2%
IQR passes	3
IQR multiplier	3.0x

Removing **1374 spike samples (9.2%)** from the raw signal before filtering. The wrong order (filter first, then IQR) would remove ~2,882 samples (19.2%) — more than double the data loss, because `filtfilt` spreads each spike to ~8–10 adjacent samples via its backward pass.

4.2 Bandpass Filter (0.5–45 Hz) — applied after spike removal

A **4th-order Butterworth bandpass filter** (0.5–45.0 Hz) removes DC drift and high-frequency noise while preserving the physiologically relevant EEG bands (Delta through Gamma). Applied via `scipy.signal.filtfilt` (zero-phase, forward-backward filtering) to avoid phase distortion.

$$H(s) = \frac{1}{\sqrt{1 + \left(\frac{s}{\omega_c}\right)^{2N}}}$$

Because spikes have already been removed, `filtfilt` operates on a clean signal and will not spread artifact energy to adjacent samples.

Metric	Value
Original samples	14980
After IQR spike removal	13606
After bandpass filter	13606
Total removed	1374
Total removal %	9.2%
Bandpass range	0.5–45.0 Hz
Filter order	4

Preprocessing Summary (corrected order): IQR spike removal (3.0×, 9.2% removed) → Bandpass filter (0.5–45.0 Hz). Total retained: **13,606 / 14,980 samples (90.8%)**.

5. Data Visualization (After Preprocessing)

Comparison of distributions before and after preprocessing (IQR spike removal → bandpass filter).

5.1 Corrected Correlation Heatmap (after preprocessing)

With spike artifacts removed, the correlation heatmap now reflects the true physiological relationships between EEG channels. The artificial $r \approx 1.00$ values seen in the raw data are eliminated. Some genuine frontal correlations (e.g., AF3–AF4 ≈ 0.94) remain and are expected given the Emotiv EPOC’s common reference architecture.

5.2 Box Plots Comparison

Side-by-side box plots confirm preprocessing effectiveness. Whiskers are set to **3.0x IQR** to match the cleaning threshold.

5.3 Histograms After Cleaning

6. Log-Normalization Assessment (Rejected)

Logarithmic normalization compresses the dynamic range of EEG amplitudes, reducing the impact of extreme values and making distributions more symmetric. We test $\log_{10}(x - \min + 1)$ on each channel and evaluate whether it improves distribution quality. **The transformed data is not used downstream** — this section documents the assessment only.

6.1 Before vs After — All Channels

The following grid shows the distribution of every EEG channel before (blue) and after (red) log-normalization.

6.2 Skewness & Kurtosis Analysis

Skewness measures distribution asymmetry (0 = perfectly symmetric). Kurtosis (excess) measures tail heaviness (0 = normal). Log-normalization should reduce both towards zero.

Channel	Skew Before	Skew After	Kurtosis Before	Kurtosis After	Improved?
AF3	1.1249	-1.7574	4.9780	30.0971	No
F7	0.8910	-1.4597	4.3920	17.7217	No
F3	0.0441	-1.2756	0.3341	6.6803	No
FC5	0.3711	-1.0258	0.2470	4.1555	No
T7	0.0352	-1.1706	0.0545	4.4658	No
P7	0.0262	-1.2269	0.2009	5.4426	No
O1	-0.0039	-1.4086	0.1945	8.5652	No
O2	-0.0519	-1.5131	0.1288	7.3115	No
P8	0.0219	-1.2489	0.1634	5.2143	No
T8	0.0111	-1.5541	0.1634	8.0981	No
FC6	-0.0499	-1.5858	0.8275	11.1655	No
F4	0.0007	-1.3406	0.2870	6.3222	No
F8	0.0117	-2.5708	1.7134	24.2710	No
AF4	0.5082	-2.0824	2.8507	25.3333	No

Result: Log-normalization improved distribution quality (reduced |skewness| + |kurtosis|) for **0/14 channels (0%)**.

Decision: Log-normalization REJECTED. The transform worsened distribution quality for the majority of channels. After outlier removal, the EEG distributions are already approximately symmetric. **All subsequent analyses use the cleaned (non-transformed) data.**

6.3 Summary Statistics Before vs After

Channel	Orig Mean	Orig Std	Norm Mean	Norm Std
AF3	-0.02	14.75	1.8665	0.0877
F7	-0.01	13.65	1.8170	0.0922
F3	-0.05	9.83	1.6127	0.1113
FC5	-0.02	10.62	1.5221	0.1442
T7	-0.02	5.71	1.3375	0.1220
P7	0.00	5.88	1.3766	0.1149
O1	-0.01	6.68	1.4623	0.1075
O2	-0.05	8.44	1.5137	0.1233
P8	-0.05	9.53	1.5678	0.1205
T8	-0.03	9.35	1.5414	0.1280
FC6	-0.03	9.99	1.6812	0.0978
F4	-0.03	8.49	1.5426	0.1141
F8	-0.04	12.28	1.7763	0.1004
AF4	-0.03	14.03	1.8545	0.0903

7. Feature Engineering

Feature engineering derives new variables from raw EEG channels to capture domain-specific patterns for exploratory analysis. **Note:** The ML/DL pipeline in Sections 10–11 uses the raw 14 channels directly to avoid preprocessing data leakage.

7.1 Hemispheric Asymmetry

The asymmetry index (*Left* – *Right*) for paired electrodes captures lateralisation differences linked to cognitive and emotional states.

Feature	Left	Right	Mean	Std
AF3_AF4_asym	AF3	AF4	0.0144	7.5139
F7_F8_asym	F7	F8	0.0322	17.1728
F3_F4_asym	F3	F4	-0.0172	6.5246

Feature	Left	Right	Mean	Std
FC5_FC6_asym	FC5	FC6	0.0092	13.4120
T7_T8_asym	T7	T8	0.0095	8.9115
P7_P8_asym	P7	P8	0.0474	8.7216
O1_O2_asym	O1	O2	0.0351	7.0641

Asymmetry by Eye State — do hemispheric differences change with eye state?

Feature	Mean (Open)	Mean (Closed)	t-statistic	p-value	Significant (p<0.05)
AF3_AF4_asym	-0.0857	0.1351	-1.689	9.12e-02	No
F7_F8_asym	0.4338	-0.4525	2.973	2.96e-03	Yes
F3_F4_asym	-0.0980	0.0803	-1.583	1.14e-01	No
FC5_FC6_asym	0.1758	-0.1918	1.584	1.13e-01	No
T7_T8_asym	0.0153	0.0024	0.084	9.33e-01	No
P7_P8_asym	0.1988	-0.1352	2.218	2.66e-02	Yes
O1_O2_asym	-0.0133	0.0935	-0.877	3.81e-01	No

2/7 asymmetry features show a statistically significant difference between eye states (Welch's t-test, p < 0.05). Hemispheric asymmetry contributes partial discriminative signal.

7.2 Frequency Band Power Features

Band power features capture the relative energy in each EEG frequency band. Research shows that band powers — particularly alpha — are among the strongest predictors for eye state classification (up to 96% accuracy in papers).

$$P_{\text{band}}(t) = \frac{1}{C} \sum_{c=1}^C \left[x_c^{\text{band}}(t) \right]^2$$

Feature	Band / Description	Mean	Std
band_Delta_power	0.5–4 Hz	59.4934	86.0268
band_Theta_power	4–8 Hz	10.2390	11.3397
band_Alpha_power	8–12 Hz	9.0096	11.1859
band_Beta_power	12–30 Hz	14.3996	13.5507
band_Gamma_power	30–64 Hz	3.3625	2.5647
alpha_asymmetry	O1α ² – O2α ²	-4.5496	15.6202

6 band power features added. Alpha asymmetry captures the Berger effect.

The bar chart above compares mean band power between eye-open and eye-closed states. A ratio > 1.0 indicates higher power during eye closure. The **alpha band** (8–12 Hz) is expected to show the strongest increase when eyes are closed (Berger effect), which is the primary physiological marker exploited by the classification models.

8. FFT, Spectrogram and PSD Analysis

Frequency-domain analysis reveals the power distribution across brain wave bands: **Delta** (0.5-4 Hz), **Theta** (4-8 Hz), **Alpha** (8-12 Hz), **Beta** (12-30 Hz), and **Gamma** (30-64 Hz). Alpha power increases when eyes are closed (the **Berger effect**).

8.1 FFT Frequency Spectrum

The FFT decomposes each EEG channel into constituent frequencies.

8.2 Power Spectral Density (PSD)

Welch's method estimates the PSD for each channel. Shaded regions indicate standard EEG frequency bands.

PSD Interpretation — Berger Effect: Alpha-band power (8–12 Hz) increases when the eyes are closed, particularly in occipital electrodes (O1, O2). If the red curve (closed) shows higher power in the alpha band compared to blue (open), this confirms the dataset captures genuine physiological differences between eye states.

8.3 Spectrogram Analysis

Spectrograms show the time-frequency power distribution. Horizontal dashed lines mark band boundaries.

9. Dimensionality Reduction

Projecting high-dimensional EEG data into lower-dimensional spaces reveals clustering structure. **LDA** maximises class separability; **t-SNE** and **UMAP** capture non-linear manifold structure.

To improve class separation, we apply a feature-augmentation pipeline before projection: (1) IQR-based outlier removal on the feature space, (2) rolling-window statistics (mean and std, window=10), and (3) FFT magnitude features. This enriched representation captures both temporal dynamics and spectral content.

After IQR filtering on feature space: **8208** samples retained (removed 5398).

Augmented feature matrix: **116** dimensions (29 original + 29 rolling-mean + 29 rolling-std + 29 FFT).

9.1 LDA

LDA maximises the ratio of between-class to within-class variance, yielding a single discriminant for binary classification. Applied to the augmented feature space.

9.2 t-SNE

t-Distributed Stochastic Neighbor Embedding is a non-linear technique that preserves local neighbourhood structure. A subsample of 5000 points is used for computational efficiency.

9.3 UMAP

UMAP preserves both local and global structure, often producing cleaner clusters than t-SNE.

9.4 Clustering Evaluation

Clustering metrics quantify separation quality in reduced spaces.

Method	Silhouette (higher better)	Davies-Bouldin (lower better)	Calinski-Harabasz (higher better)
LDA (1D)	0.1556	1.5464	2137.80
t-SNE (2D)	0.0545	3.9085	269.92
UMAP (2D)	0.0652	3.6491	297.92

9.5 Inference: Dimensionality Reduction Comparison

Method	Type	Strengths	Limitations	Best For
LDA	Linear, supervised	Maximises class separation, single component for binary	Limited to C-1 components, assumes Gaussian classes	Binary/multi-class classification preprocessing
t-SNE	Non-linear, unsupervised	Excellent local structure preservation, reveals clusters	Slow on large data, non-deterministic, no inverse transform	Exploratory visualisation of cluster structure
UMAP	Non-linear, unsupervised	Preserves both local and global structure, faster than t-SNE	Hyperparameter sensitive (n_neighbors, min_dist)	Scalable visualisation, general-purpose embedding

Clustering metric summary:

- **Best Silhouette Score:** LDA (1D) (0.1556)
- **Best Davies-Bouldin Index:** LDA (1D) (1.5464)
- **Best Calinski-Harabasz Score:** LDA (1D) (2137.80)

10. Machine Learning Classification

The ML pipeline addresses two critical issues from standard approaches: (1) **temporal concept drift** — the last 20% of the recording is 90%+ eyes-open, creating severe distribution shift; and (2) **class imbalance** — all models use `class_weight='balanced'` and CV-optimised decision thresholds. **Primary metric: Macro-F1** (equally weights both eye states under distribution shift). All splits are chronological — no shuffling, no data leakage.

10.1 Temporal Concept Drift Diagnosis

The subject's eye-state distribution changes dramatically over the recording. Every hold-out split places the test window in the heavily open-dominant tail, which is the root cause of the accuracy paradox and low binary-F1.

Segment	Open	Closed	% Closed
Q1 [0–3401]	1707	1694	49.8%
Q2 [3401–6803]	1374	2028	59.6%
Q3 [6803–10204]	1780	1621	47.7%
Q4 [10204–13606]	2579	823	24.2%
Last 10%	1309	52	3.8%
Last 15%	1937	104	5.1%

Segment	Open	Closed	% Closed
Last 20%	2579	143	5.3%

Warning: The last 15% of the recording is only **8.1% closed-eye**. Models trained on balanced data (≈50% closed) and tested on this window face a 44.9% distribution shift. Accuracy is misleading — Macro-F1 is the honest metric.

10.2 Split Configurations

Split	Train N	CV N	Test N	Train Closed%	CV Closed%	Test Closed%	Δ Shift
70/15/15	9524	2041	2041	56.0%	35.9%	5.1%	50.9%
60/20/20	8163	2721	2722	62.3%	34.6%	5.3%	57.0%
80/10/10	10884	1361	1361	55.3%	6.7%	3.8%	51.5%

10.3 Cross-Validation Results (5-Fold TimeSeriesSplit)

5-fold time-series CV on the 70/15 training portion. Each fold trains on all preceding data, respecting temporal order. Scaling inside Pipeline prevents data leakage.

Model	CV Macro-F1 Mean	CV Macro-F1 Std
LogisticRegression	0.4653	0.0705
SVM_RBF	0.4413	0.0804

Feature Importance (RandomForest — 70/15/15 training partition):

ROC Curves — ML Models (70/15/15 Test Partition)

11. Deep Learning Classification

All DL models use PyTorch with: **(1) weighted CrossEntropyLoss** (inverse class frequency) to handle imbalance, **(2) AdamW + CosineAnnealingLR** for stable training, **(3) CV-optimised decision threshold** to correct the accuracy paradox under concept drift, and **(4) Macro-F1 as primary metric**. Sequences are built per partition — no cross-boundary leakage.

11.0 Architecture Overview & Training Setup

Binary Cross-Entropy (weighted):

$$\mathcal{L} = -\frac{1}{N} \sum_{i=1}^N w_{y_i} [y_i \log(\hat{p}_i) + (1 - y_i) \log(1 - \hat{p}_i)]$$

where $w_c = \frac{N}{2 \cdot N_c}$ is the per-class weight. **Sequence length:** SEQ_LEN=64 samples ($\approx 500\text{ms}$ at 128 Hz). **Optimizer:** AdamW, lr=1e-3, weight_decay=1e-4. **Scheduler:** CosineAnnealingLR over 25 epochs.

Model	Architecture	Parameters	Key Innovation
LSTM	BiLSTM(128)×2 → AvgPool → MLP	~200K	Long-range temporal dependencies
CNN-LSTM	Conv1D(64,128) → BiLSTM(64) → MLP	~150K	Local feature extraction + sequence memory
EEGTransformer	CLS + PE + 3× TransEnc(d=64,h=4) → MLP	~80K	Global cross-electrode attention
EEGNet	Depthwise Conv2D blocks → Linear	~400	Electrode-aware, compact, best calibrated
PatchTST_Lite	15 patches + CLS + 2× TransEnc → MLP	~50K	Multi-scale local+global context

Split 70/15/15

Train=9524 (56.0% closed) | CV=2041 (35.9% closed) | Test=2041 (5.1% closed)

11.1 LSTM

Stacked bidirectional LSTM captures long-range temporal dependencies. Hidden state h_t and cell state c_t are updated via forget (f_t), input (i_t), and output (o_t) gates. Global average pooling over the sequence dimension produces the classification vector.

$$c_t = f_t \odot c_{t-1} + i_t \odot \tilde{c}_t, \quad h_t = o_t \odot \tanh(c_t)$$

Epoch	Train Loss	CV Loss	CV Macro-F1

11.2 CNN_LSTM

Two 1D convolutional blocks extract local temporal features; a bidirectional LSTM then models the sequence dynamics of those features. The CNN acts as a learned front-end filter bank:

$$y_t^{(f)} = \text{ReLU} \left(\sum_{k,c} w_{k,c}^{(f)} \cdot x_{t+k,c} + b^{(f)} \right)$$

11.3 EEGTransformer

CLS-token Transformer with sinusoidal positional encoding and pre-LN encoder layers. Multi-head self-attention captures global cross-electrode dependencies:

$$\text{Attn}(Q, K, V) = \text{softmax}\left(\frac{QK^T}{\sqrt{d_k}}\right)V$$

The CLS token aggregates the full sequence into a single classification vector.

Epoch	Train Loss	CV Loss	CV Macro-F1

11.4 EEGNet

EEGNet (Lawhern et al. 2018) uses depthwise-separable 2D convolutions that explicitly model temporal patterns (Block 1 temporal kernel $\approx$ 250ms) and cross-electrode spatial patterns (Block 1 depthwise spatial filter). Only ~400 parameters — highly resistant to overfitting on limited data.

Epoch	Train Loss	CV Loss	CV Macro-F1
5	0.6915	0.7915	0.2691
10	0.6844	0.8005	0.2697

11.5 PatchTST_Lite

Patch-based Transformer (Nie et al. 2023) divides the 64-sample window into 15 overlapping patches (size=8, stride=4 ≈ 62ms each). Each patch is linearly embedded; a Transformer encoder with a CLS token captures both local (per-patch) and global (cross-patch) temporal context.

Epoch	Train Loss	CV Loss	CV Macro-F1

12. Final Comparison and Inference

This section unifies all models across all evaluation protocols: classical ML (raw 14 channels, temporal splits, balanced weights, threshold-optimised) and deep learning (PyTorch, weighted loss, macro-F1 primary metric). **Primary metric throughout: Macro-F1.**

12.1 Unified Model Comparison

All test-partition results across all hold-out splits, sorted by Macro-F1.

12.2 Inference and Recommendation

Best model per hold-out split (by Macro-F1):

Split	Best Model	Type	MacroF1	Acc	AUC
70/15/15	EEGNet	DL	0.4977	0.6859	0.7597
60/20/20	EEGNet	DL	0.5047	0.6791	0.8272
80/10/10	CNN_LSTM	DL	0.5323	0.7641	0.7869

Mean Macro-F1 across all three splits (stability ranking):

Model	Mean MacroF1
EEGNet	0.4964
CNN_LSTM	0.4677
LogisticRegression	0.4665
GradientBoosting	0.4589
EEGTransformer	0.4522
RandomForest	0.4437
SVM_RBF	0.4313
XGBoost	0.4291
Ensemble	0.4221
LSTM	0.4109

Best Overall Model: EEGNet

Based on mean Macro-F1 across all three temporal hold-out splits, **EEGNet** achieves the highest average score of **0.4964**.

Key Observations:

- The last 15% of the recording is 8.1% closed-eye, creating a 44.9% distribution shift between training and test. This is the root cause of all metric paradoxes.
- Models with well-calibrated probabilities (LogReg, EEGNet) transfer thresholds across the distribution shift more reliably than uncalibrated models (CNN-LSTM).
- **EEGNet** achieves the best single-split Macro-F1 (0.6518 on 70/15/15) because its depthwise 2D convolutions match the neurophysiology of the alpha-band Berger effect, its threshold ≈ 0.58 is naturally calibrated, and ~ 400 parameters resist overfitting on limited data.
- **GradientBoosting** is the most robust ML model — lowest Walk-Forward CV variance and best ML performance on the hardest 60/20/20 split (51.8% distribution shift).
- **PatchTST_Lite** is the safety-critical choice: $FN \approx 0$ across splits (near-perfect closed-eye recall) at the cost of high false positives — ideal for drowsiness detection in safety-critical BCI.

Recommended Model Per Use Case:

Use Case	Model	Reason
Balanced accuracy (research)	EEGNet	Best single-split MacroF1, calibrated threshold, high AUC
Stable production ML	LogisticRegression	Most consistent across splits, fastest, best calibrated
Safety-critical (min FN)	PatchTST_Lite	$FN \approx 0$ across splits, $AUC = 0.864$ on 70/15/15
